

JPA Assignment

Your assignment is to create a RecipeDatabase with the help of:
Spring Boot, JPA/Hibernate, MySQL and H2.

Subjects:

- JPA / Hibernate
- Entity
- Spring Boot
- Dependency Injection
- Entity Relationships
- SpringData / EntityManager
- CRUD functionality with SpringData or EntityManager
- Read from database with help of Spring Data framework or queries.
- MySQL database
- H2 database in testing environment.
- Testning with database.

Requirements:

- All Entities and relations need to be in place.
- Implement Create, Read, Update, Delete and specified functionalities with Repositories or Dao classes.
- The following functionalities need to tested with JUnit.
 - Add and remove from collections in you Entities (e.g. List, Set etc.).
 - The methods you specified or implemented in Repositories or Dao classes.

Optional:

- Implement service layer according to description.

Submit:

- Publish to GitHub and send the link.

Entities

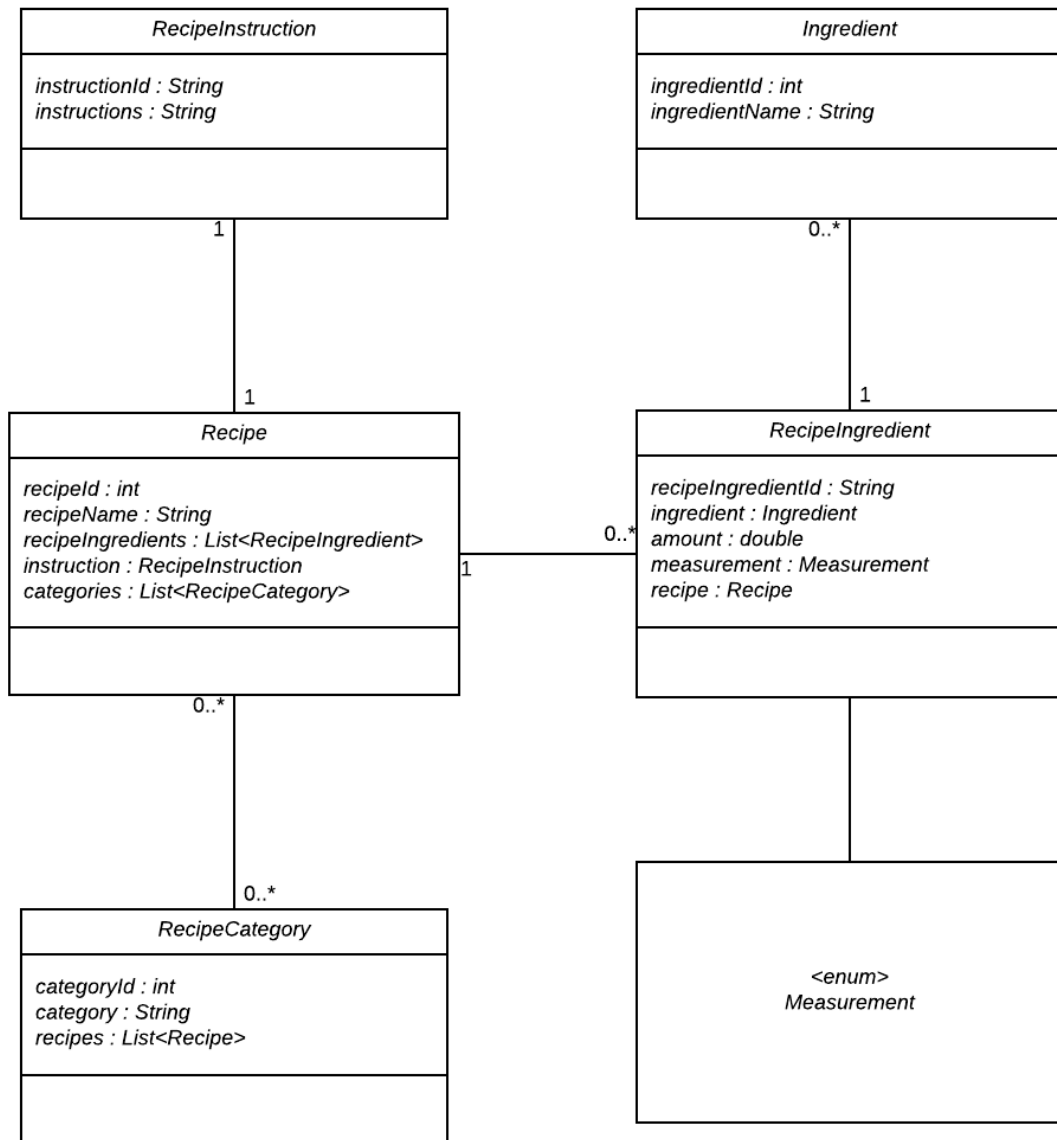

Create these Java files with the following:

1. **Class: Ingredient**
 - a. Contains an id of type int.
 - b. Contains a unique ingredient.
2. **Enum: Measurement**
 - a. Specify a couple of measurements and weights that you may find suitable for a recipe.
e.g. TBSP, TSP, G, HG, KG, ML, CL, DL etc.
3. **Class: RecipeIngredient**
 - a. Contains an id of type String. Generate the id as a UUID from Hibernate.
 - b. Contains a reference to Ingredient.
 - c. Contains a representation of a measured amount type double.
 - d. Contains a Measurement that represent the unit.
 - e. Contains a reference to the associated Recipe.
4. **Class: RecipeCategory**
 - a. Contains an id of type int.
 - b. Contains a category of type String.
 - c. Contains a collection of recipes associated to this RecipeCategory.
5. **Class: Recipe**
 - a. Contains an id of type int.
 - b. Contains a recipe name of type String.
 - c. Contains a collection of recipe ingredients. When you remove content from this collection make sure to implement automagical removal of this RecipeIngredient.
 - d. Contains recipe instructions of type RecipeInstruction.
 - e. Contains a collection of RecipeCategory.
6. **Class: RecipeInstruction**
 - a. Contains an id of type String. Generate the id as a UUID from Hibernate.
 - b. Contains recipe instructions of type String

Class Diagram on next page.

Class Diagram

These are the relationships in Java.

Note!

You chose the variable names and the type of collection in this assignment.

0..* Read this as none to many.

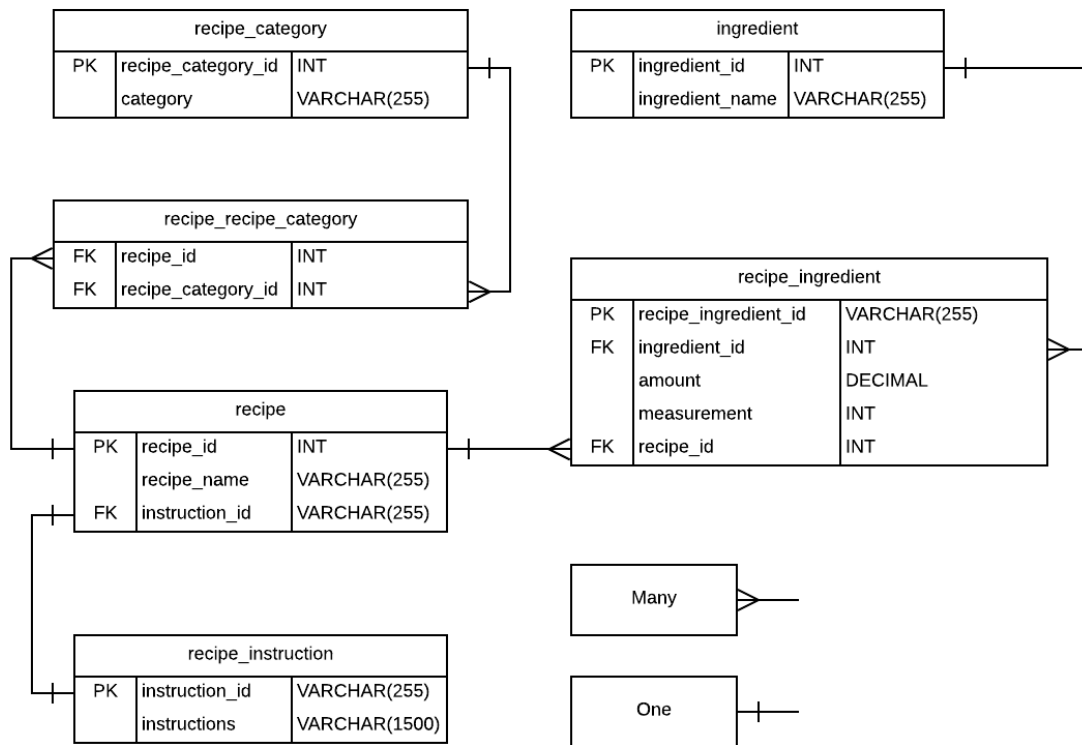

1 Read this as just one.

Entity Relationship diagram on next page.

Database Diagram

(Entity Relationship diagram)

These are the relationships between database tables.

Repository / Data Access Object

You have two options with accessing data.

1. Use Data Access Object classes connected with interfaces.
2. Use Spring Data and create repositories.

Implement CRUD operations and the following functionalities:

- Ingredient Repository/Dao:
 - Search for a specific ingredient name by specified String.
 - Search for ingredient that name particularly corresponded with search string.
- Recipe Repository/Dao:
 - Search for recipes where recipe name contains specified String.
 - Search for all recipes that contains a specified ingredient name.
e.g. potato, tomato, salt, etc.
 - Search for all recipes that belong to a specific recipe category.
e.g. Chicken, Vegan, Celebration, Weekend etc.
 - Search for all recipes that match one or more categories.
e.g. {"Spicy","Mexican","Weekend"}
- RecipeIngredient Repository / Dao:
 - Only specify CRUD functionality.
(Other functionalities will be handled by Recipe.)
- RecipeInstruction Repository / Dao:
 - Only specify CRUD functionality.

Don't forget to test the methods you created.

Service layer

Optional

You create service classes for the parts of a program where you want to combine or separate certain functionalities.

Create service classes for creation of entities.
e.g. `RecipeCreation`, `IngredientCreation`, `RecipeCategoryCreation`, etc.

Specify Interfaces and implement the following:

1. These services have the responsibility to collect and validate input before creation of entities.
2. When entity is created, call your Repository / Dao to save it in database.
3. Make sure to return the saved entity.
4. Test your classes with Junit.
